Abstract. In this paper, we first estimate the boundedness of a new proposed 4-dimensional (4D) hyper-chaotic system with complex dynamical behaviors. For this system, the ultimate bound set $\Omega_1$ and globally exponentially attractive set $\Omega_2$ are derived based on the optimization method, Lyapunov stability theory, and comparison principle. Numerical simulations are presented to show the effectiveness of the method and the boundary regions. Then, to prove the existence of hyper-chaos, the hyper-chaotic dynamics of the 4D nonlinear system is investigated by means of topological horseshoe theory and numerical computation. Based on the algorithm for finding horseshoes in three-dimensional hyper-chaotic maps, we finally find a horseshoe with two-directional expansions in the 4D hyper-chaotic system, which can rigorously prove the existence of the hyper-chaos in theory.

Keywords: hyper-chaotic system, ultimate bound, positively invariant set, globally exponentially attractive set, topological horseshoe.

1 Introduction

A 4D hyper-chaotic system is usually considered as a chaotic system with two positive Lyapunov exponents, which can enhance the randomness and unpredictability of the nonlinear system. So constructing a new hyper-chaotic system with complex dynamical behaviors may be more useful in some research fields, such as communication [1, 37], encryption [5, 20], and synchronization [3, 22, 31, 32].

It is well known that the dissipative chaotic system often has a typical strange attractor in its phase space and the strange attractor is usually bounded. Therefore, an interesting research topic is how to estimate the bound of the dissipative chaotic or hyper-chaotic

\footnote{This research was supported by Natural Science Foundation of China grant No. 61573199 and Tianjin Nature Science Foundation grant No. 14JCYBJC18700.}
system. The ultimate bound is very important for the study of the qualitative behavior of a hyper-chaotic system. Besides, if one can prove that a hyper-chaotic system has a globally exponentially attractive set, one concludes that the system cannot have the equilibrium points, periodic or quasi-periodic solutions, or other chaotic or hyper-chaotic attractors existing outside the attractive set, which greatly simplifies the dynamics analysis of a chaotic or hyper-chaotic system. Furthermore, the boundedness of a chaotic system also plays an important role in chaos control and synchronization [21, 23, 24]. For example, in physical process control, if we use the high gain controller, it will result in the saturation of the actuator. The closed-loop performance of the system will be poor and even unstable. By estimating the ultimate boundary of the system attractive basin, a low gain controller can be designed to effectively deal with the problem of saturation constraint. Therefore, estimating the bound of attractive basin of chaotic system is helpful to the design of chaotic system control and synchronization scheme.

Although some researchers have investigated the ultimate bound property of the chaotic systems [17, 38], this is still a very difficult task technically for some high dimension systems. Ever since the Lorenz system was put forward, its ultimate bound has been investigated by Leonov et al. [6]. Li et al. [8] extended the results in the paper [7] and estimated the ultimate bounds for the Lorenz system family. Yu and Liao [36] estimated the ultimate bound and positively invariant set for a general chaotic system, which does not belong to the known Lorenz system or the Chen system, or the Lorenz family. Recently, by using the Lagrange multiplier method and set operations, Wang et al. [27] have estimated two kinds of explicit ultimate bound sets for a novel hyper-chaotic system. Therefore, it is meaningful to investigate the boundedness of the new proposed hyper-chaotic system based on the optimization method, Lyapunov stability theory, and comparison principle.

Besides, it is well known that, to prove the existence of hyper-chaos, the common method is calculating the Lyapunov exponents. However, numerical error is difficult to avoid [16], which makes this method not precise enough. The more reliable method is to verify the existence of hyper-chaos in theory. Topological horseshoe theory provides a more simple and convenient method to prove the existence of chaotic attractors, which is precisely effective. The method makes use of symbolic dynamics to study and describe the chaos from the invariant set. By combining the topological horseshoe theory with numerical simulations, it can not only give strict mathematical proof, but also reveal the dynamical mechanism [4, 19, 25].

The topological horseshoe theory has gradually shown its importance since Li and Yang [11] introduced it into the verification of hyper-chaotic system. Using the two-dimensional tensile horseshoe, the hyper-chaotic generation mechanisms of some classical systems have been strictly analyzed, and the existence of hyper-chaos has been also mathematically verified, such as MCK hyper-chaotic circuit [33], hyper-chaotic Henon mapping [12], Rössler hyper-chaotic system [9], the double coupling bridge oscillator system [13], and spacecraft power system [14], and so on. However, these achievements were only case researches and did not present a general algorithm. The reason is that it is too hard to find a topological horseshoe in a hyper-chaotic system due to the high dimension of the system and the multiple expansion directions in the state space. As we all know, a hyper-chaotic system usually has a large negative LE, its attractor is often

https://www.mii.vu.lt/NA
Ultimate boundary estimations of a hyper-chaotic system

contracted closely to a certain surface. Based on this feature, we can use a remarkable algorithm proposed by Li and Tang [16] to detect a horseshoe with two-directional expansions effectively by deducting the dimension along the direction of contraction.

Motivated by the above discussions, a new 4D smooth quadratic autonomous hyper-chaotic system is constructed directly, and the complex dynamical behaviors are studied. We first investigate the boundedness of the new hyper-chaotic system. The ultimate bound and the positively invariant set $\Omega_1$ are obtained, which is based on the optimization method and the comparison principle. Then we discuss the relationship between ultimate bound and the two positive Lyapunov exponents of the system. Besides, we find the globally exponentially attractive set $\Omega_2$ of the system and conclude that the trajectories of the system go from the exterior of $\Omega_2$ to the interior of $\Omega_2$ at exponential rate. Here we use a combination of Lyapunov stability theory with the comparison principle method. Secondly, since the values of the two positive Lyapunov exponents are not large enough to tolerate the numerical errors during the computation, we give the computer-assisted verification of hyper-chaos. Based on the algorithm for finding horseshoes in three-dimensional hyper-chaotic maps, we find a horseshoe with two-directional expansions in the 4D hyper-chaotic system, which can rigorously prove the existence of the hyper-chaos in theory.

The organization of this paper is as follows. In Section 2, we will introduce mathematical model and study complex dynamical behaviors of the new proposed 4D hyper-chaotic system. In Section 3, we will estimate the boundedness of the new 4D hyper-chaotic system including the ultimate bound and the positively invariant set $\Omega_1$ and the globally exponentially attractive set $\Omega_2$. In Section 4, we will give the computer-assisted verification of hyper-chaos by virtue of the algorithm for finding horseshoes in three-dimensional hyper-chaotic maps. Finally, conclusions will be drawn in Section 5.

2 Mathematical model and complex dynamical behaviors

The new proposed 4D hyper-chaotic system is given as follows:

$$
\begin{align*}
\dot{x} &= ay - ax + ew, \\
\dot{y} &= bx - y - xz + w, \\
\dot{z} &= -cz + xy, \\
\dot{w} &= -ky - dw - gxz,
\end{align*}
$$

where $a, b, c, d, e, g, k$ are positive constant parameters determining the chaotic and hyper-chaotic behaviors of system (1).

2.1 Symmetry and invariant set

Since system (1) is invariant under the coordinate transformation $(x, y, z, w) \to (-x, -y, z, -w)$, it is symmetrical about $z$-axis. $z$-axis is a positively invariant set of system (1), and we can get the equation $\dot{z} = -cz$ when the system is restricted to the $z$-axis. Since the solution of the equation is...
\[ z(t) = z(t_0) e^{-c(t-t_0)}, \] the trajectories from arbitrary point on the \( z \)-axis will tend to \((0, 0, 0, 0)\) when \( t \to \infty \).

### 2.2 Dissipation

Denote \( V(t) \) as the volume element and \( f \) as the vector field with components \((\dot{x}, \dot{y}, \dot{z}, \dot{w})\). According to the divergence theorem, we can get the following equation:

\[
\frac{1}{V} \frac{dV}{dt} = \sum_{i=1}^{N} \frac{\partial f_i}{\partial x_i} = \nabla f = \frac{\partial \dot{x}}{\partial x} + \frac{\partial \dot{y}}{\partial y} + \frac{\partial \dot{z}}{\partial z} + \frac{\partial \dot{w}}{\partial w} = -(a + c + d + 1) < 0.
\]

So system (1) is dissipative. That is to say, for the initial volume element \( V(0) \), \( V(t) = V(0) e^{-(a+c+d+1)t} \) indicates that each volume element containing the trajectory of the system shrinks to zero at an exponential rate, and its dynamics behavior will be fixed on an attractor [28, 29]. Thus, system (1) is globally bounded.

### 2.3 The stability of equilibria

Before the detailed analysis, the study of equilibria is necessary. \( S_0 = (0, 0, 0, 0) \) is always a equilibrium point of system (1). Other equilibrium points can be shifted to \( S_0 \) by means of coordinate translation, so we just consider the stability of \( S_0 \). For the zero equilibrium point \( S_0 \), the characteristic equation is

\[
\varphi(\lambda) = (\lambda + c) \left[ \lambda^3 + (a + d + 1) \lambda^2 + (a + d + k - ab + ad) \lambda + ad + ak - abd \right] = 0.
\]

When \( a = 18, b = 60, c = 8, d = 0.2, e = 0.1, g = 0.1, k = 10, a + d + k - ab + ad < 0 \), the characteristic equation at least has one positive real eigenvalue. Therefore, the equilibrium point \( S_0 \) is unstable, which indicates that the system will generate chaos and hyper-chaos. The stability of the other equilibrium points of the system can be verified by the same method.

### 2.4 The rich dynamics evolution

The rich dynamics evolution of system (1) can be analyzed by Lyapunov exponents (LEs) spectrum, bifurcation diagram, and various phase portraits. Lyapunov exponents are the characteristic quantity obtained by the average of system’s infinite long orbit and can be used to determine the existence and complexity of chaos and hyper-chaos. Now, the commonly used methods of calculating the LEs are QR decomposition method [2] and Wolf method [30]. In our paper, we use the QR decomposition method to calculate the LEs with the variation of parameter \( c \). Bifurcation diagram is a intuitive representation of the system evolutionary process. The key to drawing bifurcation diagram is to find a suitable Poincaré section. The horizontal axis of bifurcation diagram is the system parameter, while the vertical axis is the value of a state variable. In our paper, we give the bifurcation diagram versus parameter \( c \).

Ultimate boundary estimations of a hyper-chaotic system

Figure 1. The Lyapunov exponents spectrum versus $c \in [0, 12]$ with $a = 18, b = 60, d = 0.2, e = 0.1, g = 0.1, k = 10$.

Figure 2. The bifurcation diagram versus $c \in [0, 20]$ with $a = 18, b = 60, d = 0.2, e = 0.1, g = 0.1, k = 10$.

Let $a = 18, b = 60, d = 0.2, e = 0.1, g = 0.1, k = 10$, and the parameter $c$ varies. Denote the four LEs of system (1) by $L_1, L_2, L_3, L_4$, which satisfy $L_1 > L_2 > L_3 > L_4$. The LEs spectrum and the corresponding bifurcation diagram versus $c$ are shown in Figs. 1 and 2, respectively. With the variation of parameter $c$, system (1) undergoes periodic, quasi-periodic, chaotic, and hyper-chaotic state. The typical attractors are shown.
in Figs. 3 and 4. Figure 3 shows phase portraits of quasi-periodic and periodic attractors of system (1). Figure 4 shows phase portraits of chaotic and hyper-chaotic attractors of system (1). Especially, the system is in hyper-chaotic state when $c = 8$, the four LEs are $L_1 = 0.7742$, $L_2 = 0.6539$, $L_3 = -0.0001$, $L_4 = -28.6280$. 

https://www.mii.vu.lt/NA
3 Boundedness of the new hyper-chaotic system

3.1 Preliminary

In this subsection, we will introduce some basic definitions, which are necessary for proving the proposed theorems in the following two subsections.

Consider the following autonomous system:

$$\dot{X} = f(X),$$

(2)

where $X = (x_1, x_2, \ldots, x_n)^T \in \mathbb{R}^n$, $f : \mathbb{R}^n \to \mathbb{R}^n$, $t_0 > 0$ is the initial time, $X(t, t_0, X_0)$ is the solution, which satisfies $X(t_0, t_0, X_0) = X_0$. Suppose $\Omega \subset \mathbb{R}^n$ is a compact set, and the distance between $X(t, t_0, X_0)$ and $\Omega$ is defined by

$$\rho(X(t, t_0, X_0), \Omega) = \inf_{X \in \Omega} \|X(t, t_0, X_0) - \hat{X}\|.$$

Denote $\Omega_\varepsilon = \{X \mid \rho(X, \Omega) < \varepsilon\}$. Thus, one gets $\Omega \subset \Omega_\varepsilon$.

**Definition 1.** (See [26].) Suppose $\Omega \subset \mathbb{R}^n$ is a compact set satisfying

$$\lim_{t \to \infty} \rho(X(t), \Omega) = 0$$

for all $X_0 \in \mathbb{R}^n \setminus \Omega$, that is, for any $\varepsilon > 0$, there exists $T > t_0$ satisfying $X(t, t_0, X_0) \in \Omega_\varepsilon$ for all $t \geq T$. Then the set $\Omega$ is called an ultimate bound of system (2). If for any $X_0 \in \Omega$ and all $t \geq t_0$, $X(t, t_0, X_0) \in \Omega$, then $\Omega$ is called the positively invariant set for system (2).

**Definition 2.** (See [18].) For autonomous system (2), if there exist generalized positive definite and radially unbounded Lyapunov function $V(X(t))$ and constants $L > 0$, $\beta > 0$, for all $X_0 \in \mathbb{R}^n$, when $V(X(t)) > L$, $V(X_0) > L$, $t > t_0$, the following inequality is satisfied:

$$V(X(t)) - L \leq [V(X_0) - L]e^{-\beta(t-t_0)},$$

then

$$\Omega = \left\{X \mid \lim_{t \to +\infty} V(X(t)) \leq L \right\}$$

is said to be a globally exponentially attractive set of system (2).

3.2 The ultimate bound and positively invariant set

In this subsection, we will estimate the ultimate bound and positively invariant set of the system for $a > 0$, $b > 0$, $c > 0$, $d > 0$, $e > 0$, $g > 0$, $k > 0$. Before the detailed study, let us introduce the following lemma.

Lemma 1. Define a set $\Gamma = \{(x, y, z, w) \mid x^2/\alpha^2 + y^2/\beta^2 + (z - \bar{c})^2/c^2 + w^2/\delta^2 = 1,$
$\bar{a} \neq 0, \bar{b} \neq 0, \bar{c} \neq 0, \bar{d} \neq 0\}$ and $G(x, y, z, w) = x^2 + y^2 + z^2 + w^2,$ $H(x, y, z, w) = x^2 + y^2 + (z - 2\bar{c})^2 + w^2,$ $(x, y, z, w) \in \Gamma.$ Then we can get

$$G_m = \max_{(x, y, z, w) \in \Gamma} G = H_m = \max_{(x, y, z, w) \in \Gamma} H$$

$$= \begin{cases} 
\frac{\bar{a}^4}{\alpha^4 + \beta^4}, & \bar{a} \geq \bar{b}, \bar{a} \geq \bar{d}, \bar{a} \geq \sqrt{\bar{c}}, \\
\frac{\bar{b}^4}{\beta^4 + \gamma^4}, & \bar{b} > \bar{a}, \bar{b} > \bar{d}, \bar{b} \geq \sqrt{\bar{c}}, \\
\frac{\bar{d}^4}{\delta^4 + \gamma^4}, & \bar{d} > \bar{a}, \bar{d} > \bar{b}, \bar{d} \geq \sqrt{\bar{c}}, \\
\frac{\bar{c}^2}{4\bar{c}^2}, & \bar{a} < \sqrt{\bar{c}}, \bar{b} < \sqrt{\bar{c}}, \bar{d} < \sqrt{\bar{c}}.
\end{cases}$$

Proof. It can be easily proved by the Lagrange multiplier method. \qed

By Lemma 1, we can get the following theorem.

Theorem 1. For $a > 0, b > 0, c > 0, d > 0, e > 0, g > 0, k > 0, h > 0,$ the following set is the ultimate bound and positively invariant set of the system:

$$\Omega_1 = \left\{(x, y, z, w) \mid x^2 + hy^2 + h\left(z - \frac{a + hb}{h}\right)^2 + \frac{e}{g}w^2 \leq R^2\right\}, \quad (3)$$

Here

$$R^2 = \begin{cases} 
\frac{(a+hb)^2c^2}{4h(a-c)} & a \leq 1, a \leq d, c \geq 2a, \\
\frac{(a+hb)^2c^2}{4h(c-1)} & a > 1, a \leq d, c \geq 2, \\
\frac{(a+hb)^2c^2}{4h(c-1)} & a > d, a \leq d, c \geq 2d, \\
\frac{(a+hb)^2c^2}{4h(c-1)} & c < 2a, a \geq 2, c \leq 2d.
\end{cases}$$

Proof. Define the following generalized positive definite and radially unbounded Lyapunov function:

$$V_1 = x^2 + hy^2 + h\left(z - \frac{a + hb}{h}\right)^2 + \frac{e}{g}w^2, \quad (4)$$

where $h = ke/g > 0.$ Computing the derivative of $V_1$ along the trajectory of system (1), we can obtain

$$\frac{dV_1}{dt} = 2x\dot{x} + 2hy\dot{y} + 2h\left(z - \frac{a + hb}{h}\right)\dot{z} + 2\frac{e}{g}w\dot{w}$$

$$= 2(xy - ax + czw) + 2hy(bx - y - zw)$$

$$+ 2h\left(z - \frac{a + hb}{h}\right)(-cz + xy) + 2\frac{e}{g}w(-ky - dw - gwz)$$

https://www.mii.vu.lt/NA
Obviously, $V_1$ is positive definite for $a > 0$, $b > 0$, $c > 0$, $d > 0$, $e > 0$, $g > 0$, $k > 0$, $h > 0$. Let $\bar{V}_1 = 0$, then the following ellipsoidal surface $\Gamma$ can be obtained:

$$2ax^2 + 2hy^2 + 2hc\left[z - \frac{(a + hb)}{2h}\right]^2 + 2\frac{de}{g}w^2 = \frac{(a + hb)^2c}{2h}.$$  \hfill (5)

Outside $\Gamma$, $\bar{V}_1 < 0$, while inside $\Gamma$, $\bar{V}_1 > 0$. Thus, the ultimate bound of system (1) can be only reached on $\Gamma$. Since the $V_1(X)$ is a continuous function and $\Gamma$ is a bounded close set, function (4) can reach its maximum value: $\max V_1(X)_{X \in \Gamma} = R^2$ on the surface $\Gamma$ defined in Eq. (5). Obviously, the set defined by $\{(x, y, z, w) \mid V_1(X) \leq \max V_1(X), (x, y, z, w) \in \Gamma\}$ contains the solutions of system (1). By solving the following conditional extremum problem, we can get the maximum value $\max V_1(X)$:

$$\max V_1 = \max \left\{ x^2 + hy^2 + h\left(z - \frac{a + hb}{h}\right)^2 + \frac{e}{g}w^2 \right\},$$

$$\text{s.t.} \quad \frac{x^2}{(a + hb)^2/c} + \frac{hy^2}{(a + hb)^2/c} + \frac{h(z - \frac{a + hb}{2h})^2}{(a + hb)^2/c} + \frac{\frac{e}{g}w^2}{\frac{(a + hb)^2/c}{4hd}} = 1.$$  \hfill (6)

Set $x = \tilde{x}$, $\sqrt{h}y = \tilde{y}$, $\sqrt{h}z = \tilde{z}$, $\sqrt{e/g}w = \tilde{w}$ as a new variable, and denote $(a + hb)^2/c/(4ha) = \tilde{a}^2$, $(a + hb)^2/c/(4h) = \tilde{b}^2$, $(a + hb)^2/(4h) = \tilde{c}^2$, $(a + hb)^2c/(4hd) = \tilde{d}^2$, then the conditional extremum problem (6) can be transformed into the following forms:

$$\max V_1 = \max \left\{ \tilde{x}^2 + \tilde{y}^2 + (\tilde{z} - 2\tilde{c})^2 + \tilde{w}^2 \right\},$$

$$\text{s.t.} \quad \frac{\tilde{x}^2}{\tilde{a}^2} + \frac{\tilde{y}^2}{\tilde{b}^2} + \frac{(\tilde{z} - \tilde{c})^2}{\tilde{c}^2} + \frac{\tilde{w}^2}{\tilde{d}^2} = 1.$$  \hfill (7)

According to Lemma 1, we can easily get

$$\max_{(x, y, z, w) \in \Gamma} V_1(X) = R^2 = \begin{cases} \frac{(a + hb)^2/c}{4ha(c-a)}, & a \leq 1, \ a \leq d, \ c \geq 2a, \\ \frac{(a + hb)^2/c}{4h(c-1)}, & a > 1, \ d \geq 1, \ c \geq 2, \\ \frac{(a + hb)^2/c}{4h(c-d)}, & a > d, \ d < 1, \ c \geq 2d, \\ \frac{(a + hb)^2/c}{4h}, & c < 2a, \ a < 2, \ c < 2d. \end{cases}$$

Therefore, we have obtained the compact set $\Omega_1$ given in Eq. (3). According to Definition 1, since $\Gamma \subset \Omega_1$, next we will use the reduction to absurdity to prove

$$\lim_{t \to +\infty} \rho(X(t), \Omega_1) = 0.$$  \hfill (8)

Here \( X(t) = (x(t), y(t), z(t), w(t)) \). Suppose Eq. (8) does not hold, we can conclude that the orbits of system (1) are outside \( \Omega_1 \), thus \( \dot{V}_1 < 0 \) and \( V_1(X(t)) \) monotonously decreases.

Let \( \lim_{t \to +\infty} V_1(X(t)) = \check{V}_1 > R^2 \), and \( \delta = \inf_{X \in D} \{-\dot{V}_1(X(t))\} \), where \( D = \{X(t) \mid \dot{V}_1 \leq V_1(X(t)) \leq V_1(X(t_0))\} \), \( t_0 \) is the initial time. Consequently, we have that \( \delta, \check{V}_1 \) are both positive constants and \( dV_1(X(t))/dt \leq -\delta \). As \( t \to +\infty \), we can obtain

\[
0 < V_1(X(t)) \leq V_1(X(t_0)) - \delta(t - t_0) \to -\infty.
\]

This is inconsistent, thus Eq. (8) holds, it is equivalent to say that the set \( \tilde{\Omega}_1 \) is the ultimate bound set of system (1).

Then we prove that \( \Omega_1 \) is also the positively invariant set of system (1). Suppose \( V_1(X(t)) \) attains its maximum value on surface \( \Gamma \) at the point \( P_0(\tilde{x}_0, \tilde{y}_0, \tilde{z}_0, \tilde{w}_0) \). Since \( \Gamma \) is contained in \( \Omega_1 \), for any point \( X(t) \) on \( \Gamma \) and \( X(t) \neq P_0 \), we have \( \dot{V}_1 < 0 \). Thus, any orbit \( X(t) (X(t) \neq P_0) \) of system (1) will go into the set \( \Omega_1 \). When \( X(t) = P_0 \), by the continuation theorem, \( X(t) \) will also go into the set \( \Omega_1 \). Summarizing the contents above, we conclude that \( \Omega_1 \) is positively invariant set of system (1). This completes the proof.

**Numerical simulations**

(i) When \( a = 18, b = 60, c = 8, d = 0.2, e = 0.1, g = 0.1, k = 10 \), the system is in hyper-chaotic state, the four LEs: \( L_1 = 0.7742, L_2 = 0.6539, L_3 = -0.0001, L_4 = -28.6280 \). The ultimate bound and positively invariant set \( \Omega_1 \) is

\[
\Omega_1 = \{ (x, y, z, w) \mid x^2 + 10y^2 + 10(z - 61.8)^2 + w^2 \leq 391716.923 \}.
\]

(ii) When \( a = 16, b = 46, c = 6, d = 0.2, e = 0.1, g = 0.1, k = 8 \), the system is in hyper-chaotic state, the four LEs: \( L_1 = 0.5707, L_2 = 0.5029, L_3 = -0.0006, L_4 = -24.2731 \). The ultimate bound and positively invariant set \( \Omega_1 \) is

\[
\Omega_1 = \{ (x, y, z, w) \mid x^2 + 8y^2 + 8(z - 48)^2 + w^2 \leq 143006.897 \}.
\]

(iii) When \( a = 10, b = 30, c = 3, d = 0.1, e = 0.08, g = 0.06, k = 3.8 \), the system is in hyper-chaotic state, the four LEs: \( L_1 = 0.3906, L_2 = 0.3546, L_3 = -0.0003, L_4 = -14.8448 \). The ultimate bound and positively invariant set \( \Omega_1 \) is

\[
\Omega_1 = \{ (x, y, z, w) \mid x^2 + 5.07y^2 + 5.07(z - 31.97)^2 + 1.33w^2 \\ & \leq 40210.7886 \}.
\]

In Figs. 5–7, we give the phase portraits and ultimate bound of system (1) in 3D and 2D planes with corresponding parameter values. By comparison, we can find that with the variation of parameter values, the two positive LEs becomes smaller, and the corresponding \( \Omega_1 \) also becomes smaller.

Although Theorem 1 gives the ultimate bound and positively invariant set of system (1), it does not give the estimation of the trajectories rate. In Section 3.3, we will give the globally exponentially attractive set to estimate the trajectories rate.

https://www.mii.vu.lt/NA
Figure 5. The phase portraits and ultimate bound of system (1) with $a = 18$, $b = 60$, $c = 8$, $d = 0.2$, $e = 0.1$, $g = 0.1$, $k = 10$.

Figure 6. The phase portraits and ultimate bound of system (1) with $a = 16$, $b = 46$, $c = 6$, $d = 0.2$, $e = 0.1$, $g = 0.1$, $k = 8$.

Figure 7. The phase portraits and ultimate bound of system (1) with $a = 10$, $b = 30$, $c = 3$, $d = 0.1$, $e = 0.08$, $g = 0.06$, $k = 3.8$.  

3.3 The globally exponentially attractive set

The objective of this subsection is to derive the globally exponentially attractive set of the hyper-chaotic system (1).

**Theorem 2.** For all \( a > 0, b > 0, c > 0, d > 0, k > 0, e > 0, g > 0, \) and \( h > 0 \), let

\[
V(X(t)) = x^2 + hy^2 + h\left(z - \frac{a + hb}{h}\right)^2 + \frac{e}{g}w^2,
\]

\[
X(t) = (x(t), y(t), z(t), w(t)),
\]

\[
\beta = \min\{a, c, d, 1\}, \quad L = \frac{(a + hb)^2c}{\beta h}.
\]

When \( V(X(t)) > L, V(X_0) > L, t \geq t_0 \), we can get an exponential estimation of system (1) given by

\[
V(X(t)) - L \leq [V(X_0) - L]e^{-\beta(t-t_0)}.
\]

Especially, the set

\[
\Omega_2 = \left\{ X \mid x^2 + hy^2 + h\left(z - \frac{a + hb}{h}\right)^2 + \frac{e}{g}w^2 \leq L \right\}
\]

is a globally exponentially attractive set of system (1).

**Proof.** Define the following generalized positive definite and radially unbounded Lyapunov function:

\[
V(X(t)) = x^2 + hy^2 + h\left(z - \frac{a + hb}{h}\right)^2 + \frac{e}{g}w^2.
\]

Here \( h = \frac{ke}{g} > 0 \).

Computing the derivative of \( V(X(t)) \) along the trajectory of system (1) when \( V(X(t)) > L, V(X_0) > L, t \geq t_0 \), we have

\[
\frac{dV(X(t))}{dt} = 2x\dot{x} + 2hy\dot{y} + 2h\left(z - \frac{a + hb}{h}\right)\dot{z} + \frac{2e}{g}\dot{w}
\]

\[
= 2x(ay - ax + ezw) + 2hy(bx - y - xz + w)
\]

\[
+ 2h\left(z - \frac{a + hb}{h}\right)(-cz + xy) + \frac{2e}{g}w(-ky - dw - gxz)
\]

\[
= -2ax^2 - 2hy^2 - 2hc^2 + 2(a + hb)cz - \frac{2de}{g}w^2
\]

\[
= -ax^2 - hy^2 - hc\left(z - \frac{a + hb}{h}\right)^2 - \frac{de}{g}w^2
\]

\[
+ \frac{(a + hb)^2c}{h} - ax^2 - hy^2 - hc^2 - \frac{de}{g}w^2
\]
Ultimate boundary estimations of a hyper-chaotic system

\[
\begin{align*}
&\leq -\beta \left[ x^2 + hy^2 + h \left( z - \frac{a + hb}{h} \right)^2 + \frac{e}{g} w^2 \right] + \frac{(a + hb)^2 c}{h} \\
&= -\beta V(X(t)) + \frac{(a + hb)^2 c}{h} = -\beta \left[ V(X(t)) - \frac{(a + hb)^2 c}{\beta h} \right] \\
&= -\beta [V(X(t)) - L] < 0.
\end{align*}
\]

This is equivalent to say

\[
\frac{dV(X(t))}{dt} \leq -\beta [V(X(t)) - L].
\]  
(9)

By the comparison theorem and integrating both sides of formula (9) we obtain

\[
V(X(t)) \leq V(X(t_0)) e^{-\beta (t-t_0)} + \int_{t_0}^{t} \beta Le^{-\beta (t-\tau)} d\tau
\]

Thus, if \( V(X(t)) > L, V(X_0) > L, t \geq t_0 \), we have the following exponential estimation for system (1):

\[
V(X(t)) - L \leq [V(X(t_0)) - L] e^{-\beta (t-t_0)}.
\]

By the definition, taking limit on both sides of the above inequality as \( t \to +\infty \), we can get

\[
\lim_{t \to +\infty} V(X(t)) \leq L.
\]

Namely, the set

\[
\Omega_2 = \{ (x, y, z, w) \mid x^2 + 8y^2 + 8(z - 48)^2 + w^2 \leq L \}
\]

is the globally exponentially attractive set of system (1). This completes the proof. \( \square \)

**Numerical simulations**

(i) When \( a = 16, b = 46, c = 6, d = 0.8, e = 0.1, g = 0.1, k = 8 \), the system is in hyper-chaotic state, the four LEs: \( L_1 = 0.4093, L_2 = 0.2332, L_3 = -0.0002, L_4 = -24.4424 \). The globally exponentially attractive set \( \Omega_2 \) is

\[
\Omega_2 = \{ (x, y, z, w) \mid x^2 + y^2 + h \left( z - \frac{a + hb}{h} \right)^2 + \frac{e}{g} w^2 \leq L \}
\]

(ii) When \( a = 16, b = 46, c = 6, d = 0.8, e = 0.1, g = 0.1, k = 1 \), the system is in chaotic state, the four LEs: \( L_1 = 1.3422, L_2 = 0, L_3 = -1.0335, L_4 = -24.1086 \). The globally exponentially attractive set \( \Omega_2 \) is

\[
\Omega_2 = \{ (x, y, z, w) \mid x^2 + y^2 + (z - 62)^2 + w^2 \leq 28830 \}.
\]
The trajectories of system (1) are contained in $\Omega_2$ with $a = 16, b = 46, c = 6, d = 0.8, e = 0.1, g = 0.1, k = 8$.

(iii) When $a = 16, b = 46, c = 11, d = 0.8, e = 0.1, g = 0.1, k = 8$, the system is in periodic state, the four LEs: $L_1 = 0.0003, L_2 = -0.1727, L_3 = -2.8119, L_4 = -25.8157$. The globally exponentially attractive set $\Omega_2$ is
\[
\Omega_2 = \{(x, y, z, w) \mid x^2 + 8y^2 + 8(z - 62)^2 + w^2 \leq 253440\}.
\]

Through the analysis of the above conditions, we can find that the trajectories of system (1) go from the exterior of $\Omega_2$ to the interior of $\Omega_2$ at exponential rate and when $t \to +\infty$, the trajectories of system (1) are contained in $\Omega_2$ as shown in Fig. 8. That is to say, the system cannot have the equilibrium points, periodic or quasi-periodic solutions, or other chaotic or hyper-chaotic attractors existing outside the attractive set.

4 Computer-assisted verification of hyper-chaos

From the analysis in Sections 2 and 3 we can find that system (1) is hyper-chaotic for different parameters. One important difference among them is the values of two positive Lyapunov exponents. In Section 3, when parameters $a = 10, b = 30, c = 3, d = 0.1, e = 0.08, g = 0.06, k = 3.8$, the two positive Lyapunov exponents are $L_1 = 0.3906,$
Definition 3. (See [9]). Let $L = \partial D$ be a connected subset. $L$ is said to be a separation of $D^1$ and $D^2$, denoted by $L \searrow (D^1, D^2)$, if for any connected subset $L \subset D$ with $L \cap D^1 = \emptyset$ and $L \cap D^2 = \emptyset$, one has $L \cap D \neq \emptyset$.

Definition 4. (See [9,34].) Let $G \subset D$ be a connected subset. We say that $f(G)$ separates $D_j$ with respect to $D^1_j$ and $D^2_j$ if $G$ contains a compact subset $G'$ such that $f(G') \searrow (D^1_j, D^2_j)$, we denote it by $f(G) \mapsto D_j$. If $f(G) \mapsto D_j$ holds true for each subset $G \subset D$ satisfied $G \searrow (D^1, D^2)$, we say that $f : D_1 \mapsto D_j$ is a codimension-one crossing with respect to two pairs $(D^1, D^2)$ and $(D^1_j, D^2_j)$.

Theorem 3. (See [34].) If the codimension-one crossing relation $f : D_1 \mapsto D_j$, holds for $1 \leq i, j \leq m$, then there exists a compact invariant set $K \subset D$ such that $f|K$ is semiconjugate to the $m$-shift mapping. Then the entropy of $f$ satisfies $\text{ent}(f) \geq \log m$.

Sometimes for verifying existence of chaos, the assumption in Theorem 3 is not easy to be satisfied in practice. So we use the following practical corollary.

Corollary 1. (See [9].) Suppose that the map $f : D \rightarrow X$ satisfies the following assumptions:

(i) There exist two mutually disjoint compact subsets $D_1$ and $D_2$ of $D$, and $f^m|D_1$ and $f^n|D_2$ are homeomorphisms, where $m, n$ are positive integers.

(ii) $f^m(D_1) \mapsto D_1$, $f^n(D_2) \mapsto D_2$, $f^m(D_1) \mapsto D_2$, and $f^n(D_2) \mapsto D_1$.

Then there exists a compact invariant set $K \subset D$, such that $f^{m+n}|K$ is semiconjugate to the $2$-shift dynamics, and the topological entropy of $f$ satisfies $\text{ent}(f) \geq \log 2/(m + n)$.

Since $f$ in the above corollary is a homeomorphism, we are going to study a Poincaré map of system (1). By taking the hyperplane $\Pi = \{x \triangleq (x, y, z, w) \mid x = 0, \dot{x} > 0\}$ as a Poincaré cross-section, the corresponding Poincaré map $P : \Pi \rightarrow \Pi$ can be defined as follows: for each $x = (0, y, z, w) \in \Pi$, $P(x)$ is taken to be the first return point in $\Pi$ under the flow of the dynamical system with the initial condition $x$.

Different from many other studies on topological horseshoes for two-dimensional (2D) chaotic maps [10, 15, 35], it is too hard to find a horseshoe directly for three-dimensional (3D) chaotic maps due to the higher dimensionality. Hence, we utilize the
following technique to make it possible. Firstly, we deduced the dimension along the direction of contraction to get a 2D projective map. Then we detect a projective horseshoe with two-directional expansion. At last, we construct a 3D horseshoe back to the original map $P$. According to the algorithm, we find a horseshoe by three steps.

(i) Due to the large negative LE, the dynamics in this direction contract very quickly, and the hyper-chaotic attractor is often contracted closely to a curved surface whose equation $w = s(y, z)$ can be easily fitted in MATLAB. Hence, we deduce the dimension along the direction of contraction to obtain a 2D projective system.

(ii) Now, we only need to cast about for a 2D horseshoe of the projective map on the $yoz$-plane. Through several attempts, we find a horseshoe with two directional expansions by choosing two quadrilaterals in the $yoz$-plane. The four vertices of the first quadrilateral $A_{yoz}$ in terms of $(y, z)$ are $A_1 = (23.107, 0.522)$, $A_2 = (21.321, 0.125)$, $A_3 = (25.607, -1.125)$, $A_4 = (26.964, -0.639)$. The four vertices of the second one $B_{yoz}$ are $B_1 = (20.178, -0.129)$, $B_2 = (18.821, -0.282)$, $B_3 = (21.107, -1.165)$, $B_4 = (22.428, -1.075)$.

(iii) We construct the 3D horseshoe of the map $P$ utilizing the projective horseshoe by projecting the planar horseshoe back to the 3D space. Finally, we have two blocks $A$ and $B$ in the phase space of the Poincaré map $P$ as shown in Figs. 9(a) and 10(a). It is not hard to get the following theorem.

**Theorem 4.** For the Poincaré map $P : \Pi \to \Pi$, there exists a closed invariant set $A \subset A \cup B$ on which $P^{1+2}|A$ is semi-conjugate to the $2$-shift, and $\text{cut}(P) \geq \log 2/3$.

**Proof.** According to Corollary 1, we only need to show that $A$, $B$, and their images under $P$ and $P^2$ respectively satisfy the following relationships about the codimension-one crossing:

$$P(A) \mapsto A, \quad P(A) \mapsto B, \quad P^2(B) \mapsto A, \quad P^2(B) \mapsto B.$$

The geometrical relations of $A$, $B$ and $P(A)$ are shown in Fig. 9. Figure 9(a) is a 3D view, which suggests that $P(A)$ expands in two directions and transversely intersects both blocks $A$ and $B$. Figure 9(b) is a side view, which shows that the intersection happens between their top and bottom surfaces, i.e., $(A^t, A^b)$ and $(B^t, B^b)$. Figure 9(c) is a top view, which shows that the side surface of $A$ is mapped outside $A$ and $B$. Therefore, for each separation $S$ of $(A^t, A^b)$, $f(S) \cap A$ must be a separation of $(A^t, A^b)$, and $f(S) \cap B$ must be a separation of $(B^t, B^b)$. Then we have $P(A) \mapsto A, P(A) \mapsto B$. Similarly, we can have $P^2(B) \mapsto A, P^2(B) \mapsto B$ from the Fig. 10.

Since system (1) is smooth, i.e., the system has a unique solution from each initial condition. Figs. 9 and 10 also show that $P^1|A$ and $P^2|B$ are both continuous, so they must be homeomorphism. Then it follows from Corollary 1 that there exists a compact invariant set $A \subset A \cup B$ such that $P^{1+2}|A$ is semi-conjugate to the $2$-shift, and the topological entropy of $P$ is not less than $\log 2/3$. Since $P^1|A$ and $P^2|B$ both expand in two directions, the expansions along each trajectory in $A$ are also in two directions, so there must exist two positive Lyapunov exponents. Therefore, system (1) is hyper-chaotic. \(\square\)
5 Conclusion

A new 4D hyper-chaotic system with complex dynamical behaviors is presented in this paper. The Lyapunov exponents spectrum and bifurcation diagram are provided and analyzed. The periodic orbit, chaotic, and hyper-chaotic attractors can be found in this nonlinear system. Based on the optimization method, Lyapunov stability theory, and comparison principle, we have obtained the boundedness of the new 4D hyper-chaotic system including the ultimate bound and positively invariant set $\Omega_1$ and the globally exponentially attractive set $\Omega_2$. The corresponding boundedness has been verified by the numerical simulations, which show the effectiveness of the proposed scheme. Besides, by means of topological horseshoe theory and numerical simulation, a topological horseshoe with two-directional expansions has been also obtained, which can rigorously ensure that system (1) is hyper-chaotic system in theory.
